Introduction: In recent years the relationship between the systematic practice of physical exercise, cardiovascular dynamics and the functioning of the autonomic nervous system has been recognized.

Objective: To determine the modifications that nonlinear parameters undergo in the autonomic cardiovascular regulation of the heart rate variability with the systematic practice of physical exercise.

Methodological Design: Retrospective cohort analytical study in the period from February 2016 to August 2018. Universe and sample of 36 individuals (Group 1: 18 high performance baseball athletes, Group 2: 18 students from the University of Medical Sciences of Santiago de Cuba). The data were collected in the Biomedical Basic Sciences Laboratory of the University's Faculty 1, through the 8-channel PowerLab polygraph, and stored using the Kubios Software version 3.0.4 Premium.

Results: Statistically significant differences were found in heart rate values (p = 0.000); SD1 (p = 0.025); SD2 / SD1 ratio (p = 0.007); sample entropy (p = 0.011); short-term fluctuations alpha 1 (p = 0.019); linear average length (p = 0.016); linear maximum length (p = 0.001); recurrence rate (p = 0.034); determinism (p = 0.010) and Shannon
entropy ($p = 0.015$). The parameters of SD1 ($C = 906$) and sample entropy ($C = 712$) were significantly associated with a heart rate $\leq 70$ beats / min.

**Conclusions:** With the systematic practice of physical exercise, the non-linear dynamics of the autonomic cardiovascular regulation of the heart rate variability undergoes modifications that respond to a better adaptability of the autonomic nervous system, and to a greater capacity to regulate cardiovascular function.
